Detailed Description:

Vehicle Support Frame

As an established standardised freight handling format, containerisation has been proposed for vehicle transport and storage, for load handling convenience, security and protection.

The term vehicle, is primarily directed to motor cars, but in principle embraces other types such as vans, trucks, tractors and trailers, with or without on board cargo.

For economic considerations of optimal utilisation, cargo load configuration is carefully matched, to occupy the full internal container volume, allowing for some load handling and access clearance.

10 As to load capacity, containers are generally of standardised elongate rectangular form, in both plan, side and end elevation, to certain dimensions.

This rectangular form does not readily lend itself to accommodate diverse curved vehicle profiles, without significant wasted space around vehicles.

Vehicles must be restrained and buffered, to inhibit inadvertent contact with the 15 container structure, or other vehicles and consequent impact and abrasion damage to vulnerable body panels, in container (un)loading, handling and transit.

Prior Art

Already, some tens of thousands of vehicles (annually) are transported in containers.

However, even though vehicle containerisation has been known and adopted for decades, important needs and considerations have not been met.

Nevertheless, the challenge remains of using more of the millions of containers available worldwide.

Moreover, millions of cars are presently shipped exposed, which could travel in containers..

Proposals have been made for containers with bespoke vehicle restraint, mounting or even mutual stacking frames. These have commonly included somewhat bulky intrusive, inflexible structures restricting volumetric capacity and payload.

Vehicle stacking has hitherto adopted a simple tiered approach, requiring the combined height of vehicles to fit within a limited container height or depth.

Moreover, the frames have limited the density, juxtaposition or proximity of vehicle packing and, by their inflexible form, have generally precluded a snug mutual profile 10 interfit.

As such, they are not intended or suitable for conversion of existing containers.

Practical issues also arise in (un)loading and accommodating operator access to and from vehicles once within container confines.

Standard containers tend to be either 8ft 6in high or 9ft 6in high (externally). Their 1 5 internal access apertures, through (end) door entrance frame are typically some 12 inches less; half taken up by the load bearing base, and half by a structured door header, located only at the door positions.

Thus, problems have been encountered with manoeuvring cars safely inside a container and fixing them securely in place.

This has proved laborious and time consuming – reflecting the need to work in a confined area around a supporting framework to hold cars in place.

Typically there are two existing approaches to vehicle containerisation.

In one approach, a vehicle is driven into a container and then a ramp framework
2
assembled over it.

The ramp is inclined at a relatively steep angle.

A second vehicle is then driven up the inclined ramp – where it is lashed in situ.

In practice, in order to lash an upper vehicle in place, an operator has to lean over an underlying bottom vehicle and framework.

Thus damage to the bottom car is a regular occurrence – making this approach unpopular.

For a less steep ramp angle, greater ramp length, or span, for a given height is required.

1 0 Thus part of the ramp is temporarily extended, beyond its shipping position.

The ramp extension is then removed and a third car driven into the container along the floor and lashed in place.

Another ramp is then assembled over it and a fourth car driven 'precariously' up the ramp and lashed in place.

5 This is time-consuming and hazardous.

Furthermore, the ramp extension now protrudes from the container end – possibly needing special support when in use.

The second common approach overcomes certain disadvantages of the first, by assembling vehicles, one above another upon a double-decked cassette.

It is also known to assemble a vehicle support frame outside a container, giving room to work.

3

Once vehicles are in place and lashed, the cargo or load module, or 'cassette' is lifted and pushed inside the container, where it is fastened internally.

However, this requires operator skill in manoeuvring combined weight of vehicles and cassette frame, typically with a forklift truck.

When discharging in either of these approaches, the cassette, or ramp, framework must be dismantled and/or withdrawn wholesale, before innermost vehicles can be pulled or driven out.

Thus, if it is desired to discharge vehicles when the container is being carried say 1.2 metres above ground level – as, say, when carried on a trailer – the (un)loading 0 becomes complicated, protracted and expensive – not least with provision of mechanised lifting devices to move ramp frames or cassettes.

If vehicles are to be discharged at a dealer's premises in the centre of a town, such a procedure in the road with industrial fork trucks is impractical.

EP 0808780 Oglio teaches a dedicated container adaptation for vehicles, using an 5 intrusive internal framework with upright side posts with guideways for support cables and locating rollers of a horizontal vehicle support platform.

The platform is elevated for vehicle stacking and is of open profile between wheel ramps to allow intrusion of an underlying vehicle bonnet or hood. In practice one vehicle largely or completely overlies another.

This assumes combined vehicle heights fit within the container depth – a consideration unlikely for contemporary tall vehicle forms, such as MPV's and 4WD's and family saloons.

The framework intrudes significantly upon overall internal load capacity, and is somewhat inflexible in achieving optimum vehicle packing densities, through closer respective profile interfit.

4

Objective(s)

Ready vehicle (un)loading, without resorting to auxiliary lifting equipment, would be advantageous.

Once known vehicle frames and cassettes are no longer needed, they have to be packed into another container for return-to-base and re-use – assuming parts are not lost, as is common, en route.

Retention of vehicle support frames within the same container being used for car transport would be advantageous – provided stowed out of the way of other general cargo.

1 0 The loading angle of known ramps and cassettes is rather steep, for tight vehicle packing, yet keeping their overall height low enough to fit through the door height on an existing container precludes use of a internal roof head or 'dead' space.

Some means to motorise the ramp, so that the loading angle could be set low or even horizontal, yet once the vehicle is on board the ramp the angle varied, would be 1 5 advantageous.

Other considerations include.

An upper vehicle support frame affects the space available for the lower vehicle.

If the support were clear of the bottom vehicle, working space for lashing and vehicle access could be much improved.

If the support frame were motorised, energy requirements of existing vehicle carriers could be considered.

These would have to lift both vehicle and support frame weight.

Road borne vehicle carriers have a prime mover able to generate considerable power,

5

to satisfy such a need.

A shipping container carries no such on-board power generator and, if needed, power would have to be supplied by a much less powerful source, such as batteries of a tractor unit, or manually.

Means to reduce power requirements of a motorised frame would be advantageous.

Statement of Invention

According to one aspect of the present invention,

A vehicle support, for a container (1 0),
comprises a frame (21, 22)9

0 suspended from one or more elements (1 99 25).

Desirably, one or more elements is of adjustable span, to vary frame disposition, such as elevation and/or tilt, from an (un)loading to a transport mode.

The (suspended) vehicle support could be used with a disparate variety of container forms, including open sided formats, such as curtain sided and flat racks.

5 Reliance is placed, upon an overlying (roof) structure, rather than side or end walls or intervening frames – although contact could be made with these for bracing and stability of suspended load.

In that sense, the support frame could be configured as a form of gantry, even crane.

The vehicle support could be configured for collapse, into a compact folded retracted condition.

To this end the vehicle support could be fitted with a retractable suspension element.

When fully collapsed, the vehicle support could be accommodated in what otherwise

6

would be a container internal head space or deadspace, representing the depth of any end frame or header rail under which loads access the container.

In practice, the vehicle support could be platform, or a frame configured as wheel ramps.

A vehicle support frame could be configured as a wheel sling, cradle or carriage, for vehicle support.

Such cradles could be hung from cables, and/or threaded (screw jack) bars or pillars, again secured to the container roof or top frame structure.

Such cable or screw lift mechanisms could also be accommodated within container 1 0 (structural) frame elements.

Adjustable bracing, [longitudinally and/or transversely] could be fitted between frame and container, such as by a screw clamp, with end buffer for location in container side wall corrugations.

A demountable loading ramp could be carried by the vehicle support, and similarly 5 retracted towards and into the roof space.

Safety ties could be fitted from the container roof, and the vehicle support frame secured to them in the elevated position, as a backup restraint to the primary lift suspension mechanism.

Embodiments

There now follows a description of some particular embodiments of vehicle containerisation according to the invention, by way of example only, with reference to the accompanying diagrammatic and schematic drawings, being an exposition of various aspects, vis.

Adaptation

7

(Figures 1 A through 1 D)

Adaptation or conversion of an otherwise standard container to accommodate vehicles, using an internal support frame;

(Retractable) Collapse

(Figures 1 A and 1 D)

A collapsible vehicle support frame configuration, allowing reversion of a container for general cargo;

Suspension

(Figures 1 A through 1 D and ...

0 Suspension of a collapsible support frame from above, in particular from a container roof; with a

compact, collapsed frame mode closely underslung to the roof underside, to allow vehicle (un)loading, substitution, or combination, with general cargo;

Tilt Mode

5 Figures 1 A through 1 D and 2A, 3A, 4A, 5A and 7A)

An elevated, adjustable, tilt mode of vehicle support, allowing closer juxtapositioning and interesting of mutually overlying vehicles;

Cable Sling

(Figures 1 A through 1 D and 7A through 7D)

Cable slung vehicle support, for vehicle disposition adjustment, with mutually inclined opposed tension bracing runs, for longitudinal restraint;

Wheel Sling, Cradle or Carriage

(Figures 6 and 7A through 7D)

8

(Free hung) cradle suspension of vehicle wheels, by transverse carriages, cradles or slings, at either or both ends.

Transverse Bracing

(Figures 2A & 2B)

Adjustable buffer, transverse bracing of vehicle support, between opposite side walls, with a profiled buffer nose for location in recesses of corrugated wall profile.

Longitudinal Bracing

(Figures 2A, 2B and 7A through 7D)

1 0 Side post location, with opposed longitudinal tension in cable suspension, of vehicle support frame, or wheel carriage; side wall locating buffer also imparts longitudinal restraint.

Floor Bracing

(Figures 3A, 3B)

1 5 Retractable bracing strut between one end of vehicle support frame or carriage and container floor, to relieve cable suspension or screw pillar jack loads at other end.

Recessed Support

(Figure 2C)

Accommodation of lateral posts, pillars or struts, or screw jacking pillar, or cable suspension runs for vehicle support frames within side wall panel corrugated profile, to minimise intrusion upon load span capacity.

Screw Jack

(Figures 5A, 5B))

9

Screw jacking pillar adjustable mounting of vehicle support frame.

Hanging Screw Pillar

(Figures 5C, 5D)

Hanging variant screw pillar variant is under tension, so admits of smaller cross-section, convenient for fit within recess of side wall corrugation; traveller with spigot can engage vehicle support frame, or vehicle wheel carriage directly, through, say, pivoted link and/or through cable suspension.

Demountable Module for Open Top Container

Vehicle support frame suspended from demountable container module, such

0 as roof extension of open top container variant; allowing collapse folded retracted mode within module profile.

Considering these aspects in relation to the drawings.

Figures 1 A through 1 D show a container adapted for vehicles, and in particular a road trailer mounted container, fitted with retractable, overhead stowable, vehicle support, 5 to allow conversion to a dedicated vehicle mode, or a mixed vehicle and general cargo load; and attendant vehicle (un) loading sequence; Thus, more specifically.

Figure 1 A shows a part cut-away side elevation of a container, with a vehicle support frame deployed and another retracted;

Figure 1 B shows the container of Figure 1 A, full to capacity with vehicles, using deployed loading, mounting and support frames, in particular for an upper vehicle layer or row; also depicting loading ramp stowage;

Figure 1 C shows an initial stage in unloading the full container of Figure 1 B, by lowering a rearward vehicle support frame and deploying an inclined (un)loading ramp;

10

Figure 1 D shows a mixed cargo conversion mode of the container shown in Figures 1 A through 1 C, with a (forward) vehicle support fully retracted from above to overlies a load-volume matched general cargo, and a rearward vehicle support frame partially lowered, in readiness for a vehicle (not shown) to be stowed at an upper level;

+

Figures 2A through 2C show a vehicle support frame for the containers of Figures 1 A through 1 D;

Thus, more specifically.

Figure 2A shows a part cut-away, perspective view of a collapsible, stowable vehicle support frame, with a cable-driven, twin track ramp, and forward pivot bar, with lateral extension provision, to locate and stabilise between opposite container side walls; Figure 2B shows an enlarged detail of an adjustable buffer, for transverse and longitudinal vehicle support platform bracing between opposed container side walls; Figure 2C shows recessed location of (slender depth) lateral support posts and 5 header beam for the vehicle support of Figure 2A;

Figure 2D shows an enlarged detail of a lateral bracing clamp, with a profiled end for the inset side posts of Figure 2C;

Figures 3A and 3B show a vehicle support frame, with supplementary end strut, also compatible with the curtain-sided container variant of Figures 4A and 4B; Thus, more specifically.

Figure 3A shows an erected and elevated inclined vehicle support frame, pivotally carried at one end between lateral posts (which may in turn run in guide tracks of a curtain sided container variant) and at the other end by cable drive, but also resting (temporarily) upon a deployed pivoted strut, bearing upon the container floor; Figure 3B shows the vehicle support frame of Figure 3A, part-retracted toward the container roof, using a cable suspension and push from below, with the end strut pivoted away from the underlying cargo space;

Figures 4A and 4B show a curtain-sided adaptation of the vehicle container of Figures 1 A through 1 D;

10 Thus, more specifically.

Figure 4A shows use of upright, lateral guidance, traveller posts, running between upper and lower curtain rail guides at each container side, to carry, through an intermediate pivot mounting, a vehicle support frame of pair wheel ramps, with a roofmounted cable suspension at one (rearward) end and a depending articulated link at

5 an opposite (forward) end;

Figure 4B shows a larger scale sectional detail of curtain guidance rail post location, of Figure 4A;

Figures 5A through 5C show screw jacking pillar vehicle support frame variants of the curtain-sided container of Figures 4A and 4B;

Thus, more specifically.

Figure 5A shows use of longitudinally-spaced, curtain rail located traveller posts, for independent adjustable support of opposite vehicle support ramp ends at each container side, allowing ramp tilting and elevation;

12

Figure 5B is an enlarged section of a screw jack pillar disposition within a lateral support post carried between upper and lower curtain side rail guides; a captive screw runner carries an inward ramp location spigot; and

Figure 5C shows a variant screw pillar jack of Figure 5A, using overhead guide rail suspended elements, with swinging link and cable suspension between respective screw runner and ramp ends; tension loading allowing a smaller screw pillar section, more readily accommodated in side wall corrugation recesses, of Figure 2C; Figure 6 shows a variant of Figures 5A and 5C, with vehicle support frame configured 10 as transverse cradles for respective front and rear wheel pairs, and independently movable upon lateral screw jacks carried between guide rails, admitting longitudinal

f

movement with variation in relative wheel carriage elevation;

Figures 7A through 7D show cable-suspended wheel cradle variants of Figure 6, with 1 5 cross-bracing and underpinning support options; Thus, more specifically.

Figure 7A shows cable suspended wheel cradles, from upper curtain rail guide tracks at each side, and supplementary depending support struts between cradle and container floor, along with opposed diagonal tension wire cross-bracing of

suspension cable mounting, for longitudinal and transverse restraint;

Figure 7B shows a variation of Figure 7A with cross-leg adjustable trestles between wheel cradles and container floor;

Figure 7C shows a variant of Figure 7B with fixed-stance, trestle frames underpinning cable suspended wheel cradles at opposite vehicle sides;

13

Figure 7D shows a variant of Figure 7C with adjustable leg, wheel cradle underpinning trestles, at one vehicle end, in a co-operative stance with a pendulum offset disposition of an otherwise freely cable suspended wheel cradle at the other end; Figure 7E shows enlarged detail of local vehicle wheel tyre protrusion below a support cradle, as a buffer, against casual impact or abrasion with, say, an underlying vehicle; Figure 7F shows vehicle (re-)orientation and (re-) disposition, about a pivot axis of (rear) wheel pairs suspended in a transverse cradle, such as of Figures 7G and 7H; Figure 7G shows a transverse wheel cradle with suspension cable stabilisation upstand and clamp;

1 0 Figure 7H shows a movable cradle upstand and clamp variant of Figure 7G; Figures 8A and 8B show an adjustable, cable double-end suspension, for a vehicle support frame – whether wheel cradles or ramps – featuring a cable support run, with pulley guidance, and associated drive screws with traveller blocks; and provision for 1 5 independent relative end height adjustment, through respective drive screw rotation; Thus, more specifically.

Figure 8A shows screw drive rotational adjustment, using a selectively coupled turning handle, for one (say, forward) vehicle ramp end (not shown);

Figure 8B shows companion screw drive rotational adjustment corresponding to that of Figure 8A, for an opposite (say, rearward) vehicle ramp end (not shown); Figure 9 shows a collapsible vehicle support frame installation within an extension module, fitted upon an open topped container.

14

Referring to the drawings, a (shipping) container 1 0 is located upon a road haulage trailer 12, drawn by a detachable tractor unit 14.

The container 1 0 side wall has been cut-away, to reveal internal installations and fittings.

Essentially, an otherwise standard container 1 0 is adapted or converted for vehicle containerisation, by internal provision of collapsible vehicle support frames 21 v 227 respectively at rearward and forward container ends.

The terms 'rearward' and 'forward' are in relation to the intended transport direction.

As such, they apply to vehicle (un)loading direction, whether driven forwards or 0 reversed.

Retractable Suspension

Vehicle support frames 21, 22 are suspended from the container roof 27, comprising a roof panel 201, top side rails 28 and top end rails 202, 203, through elongate suspension elements 19/25, 18/24, at or adjacent each end.

5 Suspension elements 19/25, 18/24 are configured for compact, retractable (collapse) folding, upwards – towards the roof 27 underside.

The suspension elements 19/25, 18/24, described later in more detail, are essentially under tension when loaded, and thus can assume slender elongate forms – more compatible with retraction or collapse folding and compact stowage.

Thus, in a fully collapsed, upward stowed position, support frames 21, 22 and attendant suspension elements 19/25, 18/24, do not intrude unduly upon the load depth capacity.

This allows through passage of either general cargo or vehicles upon a container
15
(platform) floor 17.

When deployed, support frames 21, 22 effectively create another, elevated, load tier or layer for elevated vehicle storage, above the container floor 17 – by a depth sufficient to accommodate vehicles upon the floor 17, as depicted in Figure 1 B.

Whilst two longitudinally spaced frames are depicted – consistent with the capacity of a standard container (some 40 feet) length in relation to (average) target vehicle lengths (some 10–15 feet), in principle a lesser, or even greater, number could be employed for particular vehicle forms.

Similarly, whilst dual layer or level vehicle stacking is depicted, for shallow forms, such 1 0 as convertibles, additional layers, could be contemplated, with vehicle juxtaposition and (marginal) overlap.

Partial frame forms could be employed, allowing selective support of part of a vehicle.

As depicted in Figure 2A, in a convenient configuration, support frames 21 t 22 comprise parallel vehicle wheel ramps 41, 42, suspended together at or towards their 1 5 opposite ends.

Generally, an intermediate suspension and pivot axis may be used to achieve, if not even (see-saw) balance mounting, a desired load-sharing or distribution between fore and aft suspension points.

This allows an active lift at one end, about a passive pivot at another end.

In this particular example, support frame 21 9 22 suspension is through respective.

articulated links 24/24'. 25/25' at one (forward) end; and
a cable suspension 18, 19 at the opposite (rearward) end.

In the fully-extended position, the support frames 21, 22 are inclined or tilted, with a
16
lower rearward end.

Vehicles 33, 31 upon frames 21 t 22 are tilted forward or backward, according to whether they are loaded backwards or forward, respectively.

Vehicles 31–34 generally have a tapering forward end profile and account is taken of this in stacking.

Upper deck vehicles 31, 33 are loaded facing backward, to allow their respective shallower nose, canted bonnet and windscreen sections closer to the container roof 27, and reducing the downward intrusion upon the underlying available cargo space.

Similarly, the nose, canted bonnet and windscreen sections of underlying forward1 0 facing vehicles 32, 34 on the container floor 17 can fit beneath the lower forward ends of overhanging support frames 21, 22.

The vehicles 31 through 34 are lashed, say by wheel tension straps and ties 35 (not all shown) to the associated (underlying) support surface or frame.

Resiliently deformable, cushion, buffer or padding elements (not shown) may be 1 5 positioned between proximate vehicle and container body elements, as a precaution against inadvertent impact or abrasion, upon (un)loading or transit.

The overhead suspension and pendulous mounting of the support frames 21, 22 allows a certain limited longitudinal and transverse freedom of adjustment.

Such adjustment is by manual or motorised operator shift of the links 24, 25 and cables 18, 19 – upon which support frames 21, 22 are secured, say, by the lateral side wall locking buffer 65 of Figures 2A

and 213, and displaced longitudinally by tensioning (or compressing) adjustable ties 200.

Ties 200 comprise, say, webbing straps with ratchet adjustment, anchored to an existing lashing point on the floor 17 at one end and frame 21, 22 at the other.

Such adjustment would displace the suspension elements 18/24, 19/25 away from 17 the vertical as shown and (counter) act with them in securing support frames 21, 22.

The container roof 27 may be braced or reinforced locally (not shown), along with hard mounting points for suspension elements 18/24, 19/25.

It is envisaged that the support frames 21, 22 could be stiff, light-weight structures, admitting of manual movement, lifting and collapse, with optional ancillary mechanical advantage transmission or power assisted drive, such as through cables or screw jacks.

Figure 2A shows an example, with both open lattice and platform infill, described later.

At a rear end, the container 10 has opposed paired hinged access doors 23.

10 An inclined (un)loading ramp 15, between the open doors 23, bridges between ground level 16 and the rearward edge of the container floor 17.

In Figure 1 A a lower level vehicle 32, in this case a motor car, is depicted reversed, from a parked position 32', out of the container 10, down ramp 15.

Above the vehicle 32 rear exit path is a collapse-folded rear vehicle support frame 21, 15 held compact nested close to the underside of a container roof 27 and its infill panel 201.

At the front of the container 10 another vehicle 31, sits upon a deployed (vis extended) tilt-elevated vehicle support frame 22.

The support frame 22 is suspended from the roof 27 by articulated rigid links 25 and cables 19 at front and rear ends respectively.

With the inclination or tilt of the frame 22, as the vehicle 32 is driven away, it quickly clears from risk of impact with frame 22, or another vehicle 31.

Figure 1 B depicts a full container load – of some four vehicles 31 through 34 – stacked 18 at two levels, in forward and rearward pairs.

Rearward vehicle support frame 21 has been deployed, so that a vehicle 33 is suspended from the roof 27, with a vehicle 34 located underneath, resting upon the container floor 17.

Figures 1 C and 1 D show a discharge sequence of vehicles 33, 34 from the container 10.

A reverse sequence could be used for loading.

Thus, initially, a vehicle 34 has been driven away through open end doors 23.

Another (upper level) vehicle 33 is then lowered, by extending cables 18 from the 10 roof 27.

The associated vehicle support frame 21 rotates about a (forward) end pivot 36, at its suspension point with articulated link 24 – until its opposite (rearward) end 38 contacts the container floor 17.

This enables the vehicle 33 to drive off the frame 21, on to the floor 17 – and down the 15 ramp 15.

Once support frame 21 is unloaded, cables 18 can be (re-)tensioned, (by winches described later), to

rotate the frame 21, about pivot 36, until its rearward end 38 contacts the container roof 27, or a detent abutment, as depicted in Figure 1 D.

Cables (detailed in Figures 8A and 8B) are attached between the roof 27 and forward end pivot 36, so that, by further pull on cables 18, a moment about end 38 is generated, which tends to lift pivot 36 upwards, rotating the frame 21 about the end 38.

A fully collapsed and retracted position for support frame 21 is indicated by broken line 21'.

19

Any vehicles or general cargo 29 at the front of the container 1 1 can readily be discharged, by passing underneath the collapse nested frame 21'.

As shown in Figure 2A, articulated link 25 – or more precisely split interconnected link portions 25, 25' – is mounted upon an offset pivot 51 at the roof 27, with an intermediate pivot 26 between link portions 25, 25' and a lower pivot 36 to support frame 21.

The mixed vehicle and general cargo capability of Figure 1 D allows great flexibility of container use.

Typically, cargo 29 is of a height able to pass through an end access doorway of 1 0 container 10 and so is restricted to a height somewhat less than that between floor 17 and end rail 202. A shallow roof head or dead space 204 is thus available over the internal load footprint, say for non-cargo purposes.

Reverting to Figure 1 B, (un)loading ramp 15 has been moved to a transit position 15', for shipment within the container 1 0, with its end doors 23 closed.

1 5 In practice, ramp 15 desirably comprises lightweight aluminum sections, which can be manhandled and slid inside the container 1 0, upon the container floor 17, underneath loaded vehicles 32, 34.

For ramp carriage along with the nested frames 21, 22 the ramp 15 can be lifted to an intermediate position 15'', once vehicles 31, 33 are removed.

With frames 21 o 22 raised to their collapsed nested position, ramp 15 is carried up into the roof space 205.

Various attachment points between the ramp 15 and the frames 21, 22 are envisaged, but a suitable connection point is adjacent to pivots 36, 37, or the ramp 15 could be placed on top of frames 21, 22.

20

Once a vehicle (say 31) is raised up, fully or partially, its wheels and undercarriage are fairly accessible.

Thus, with a vehicle 31 elevated, operatives can work underneath, to secure the wheels and/or other vehicle body parts to frame 22, with lashings 35.

Once a vehicle 31 is raised to its full height, close up under roof 27 and roof panel 201, another vehicle 32 can drive in, clear of any structure on either side.

There is then room for an operator (not shown) to climb out of vehicle 32, through a door (not shown), and tie the vehicle 32 with lashings or ties 35 to hoops, typically located on container side walls.

0 In Figure 2A, the combined centre of gravity of a vehicle 33 and frame 21 is denoted by po i nt 'C'.

This represents a relative load distribution or balance point, for fore and aft suspension elements.

Cable 18 tension to lift (tilt) a part-suspended weight is significantly less than for a 5 direct upward lift.

Attendant power requirements are significantly reduced, since only part of a vehicle and part of a lifting frame need be raised at a time.

Figure 2A shows a part cut-away perspective view of the forward part of an example of vehicle support frame installation 21 in Figures 1 A through 1 D.

A similar arrangement may be used for the other (forward) vehicle support assembly 22.

Two parallel (longitudinal) ramps 41, 42 are disposed to support vehicle wheels (not shown).

21

Ramps 41 @ 42 are carried at one common (forward) end, upon a transverse pivot bar 37.

The bar 37 is braced transversely and longitudinally, by location between corrugations 67 of container side wall panels, as detailed in Figure 2B.

One ramp 42 is depicted with a solid platform infill, whilst the other ramp 41 retains an open lattice, (adjustable) rung 48 ladder frame profile.

A ladder frame ramp configuration 41, may be fitted with adjustable rungs 48, so that parked vehicle wheels would nest in between.

Rung adjustment can be by their relocation in adjacent holes in side frame, to accommodate different length vehicles and wheel sizes.

Intermediate rungs 48 might not be needed, since a vehicle could roll upon the container floor 17, when travelling over the frame 22.

Wheels nested between rungs 48, when lifted by frame 22, might be arranged to project below frame 22, thereby helping to cushion accidental impact by a vehicle 5 below.

A ladder frame ramp configuration 41, may be fitted with adjustable rungs 48, so that parked vehicle wheels would nest in between.

Rung adjustment can be by their relocation in adjacent holes in side frame, to accommodate different length vehicles and wheel sizes.

Intermediate rungs 48 might not be needed, since a vehicle could roll upon the container floor 17, when travelling over the frame 22.

Wheels nested between rungs 48, when lifted by frame 22, might be arranged to project below frame 22, thereby helping to cushion accidental impact by a vehicle below.

22

A manual, or optionally motorised, or power assisted, winch 46 and cable suspension 19 carries a common one (rearward) end of the paired ramps 41, 42.

The lower ends of suspension cables 18 are attached to the frame 22 by respective winches 46.

The upper cable 18 ends are anchored to (say welded) fixtures 52 upon top side rails 28 of roof 27.

Cables 18 are inclined to the vertical V, in either or both transverse and longitudinal planes.

Thus cable 18 tension to frame 22, in a transport position, contributes to bracing, 0 against lateral swaying and braking/acceleration motion loads.

A coupling shaft 45 between winches 46 is driven by a rotary handle 49, through a reduction and transfer gearbox 47, to (un)wind cables 18.

In practice, cables 18 may comprise robust steel wire or chain, or even (nylon or polypropylene) rope.

5 Handle 49 might be replaced by a drive coupling, for a motor, such as a portable electric hand drill chuck.

Alternatively, winches 46 might be motorised, say with built-in electric motors, supplied by an external power source, or an on-board battery pack.

At the opposite and forward end to the suspension cables 19, the ramps 41, 42 of the forward support frame 22, are pivotally mounted, about shaft 37, to articulated links 25, 251.

Link 25 is in turn mounted upon an offset pivot head fixture 51, upon top side rail 28.

23

Thus, minimal preparatory work is required to adapt or convert an otherwise standard container 10 for vehicle carriage.

Essentially, installation of support frames 21, 22 involves fitment of fixtures 51 and 52.

Suitable fixtures 52 are typically already fitted internally in standard containers.

At the outboard ends of pivot shaft 37 are paired opposed laterally projecting buffers 65.

Figure 2B shows buffer 65 snugly interfitting a side wall corrugation 67, at or near floor 17.

Ideally, the buffers 65 are mounted concentrically with the pivot 37 shaft centre line, 10 so that, as the frame 22, or rather ramps 41, 42, swing about pivot shaft 37, the buffers 65 need not be relocated relative to side wall corrugations 67.

The buffer 65 itself comprises a flexible, or resiliently deformable, material, such as hard rubber.

The outboard end of buffer 65 is of complementary trapezoidal profile to the side wall 15 corrugation.

The buffer 65 is mounted upon a shaft 69, carried in a block 68, fitted to frame 22, outboard of the link 25'.

The buffer 35 can rotate freely upon the end of its mounting shaft 69.

The shaft 69 has a screw thread at 66 and an inboard mounting block 78 has a complementary threaded bore 64.

When shaft 69 is rotated, using handle 61, the buffer 65 is either displaced outward to pressed against side wall corrugation 67, or withdrawn therefrom.

24

At the other side of the frame 22 is another opposed action buffer 65.

Any lateral misalignment or longitudinal offset between wall panel corrugations at opposite sides could be accommodated by, say, an offset floating pivot head mounting for buffers 65 and/or buffer head (re-) profiling.

Similarly, buffers 65 could be profiled to fit side posts 72, as shown in Figure 2D.

Operationally, the buffers 65 would not be tightened to the walls 67 until frame 22 had to be settled into its transport position.

Thus, when both buffers 65 are displaced outward, against respective adjacent side wall corrugations 67, the vehicle support frame 22 is restrained, both transversely and 10 longitudinally, by virtue of the step or offset in the corrugation profile.

The inclined or sloping trapezoidal face of the face step transition between inner and outer wall corrugation faces affords a tapering guide for a complementary profile buffer 65 nose.

This promotes a progressive location guidance and tightening action.

1 5 A lower depending link portion 25' has a through hole 63 for shaft 69.

Thus, although buffers 65 may be clamped firmly between corrugations 67, vehicle support frame 22 hangs freely upon link portions 25'.

Thus frame 22 can still pivot, about buffer shaft 69 and/or pivot shaft 37, to accommodate frame 22 tilt or inclination.

Pivot shaft 37 is shown hollow (at one end), to accommodate clamp shaft 69.

Alternatively, pivot shaft 37 could run through a hollow clamp shaft 69.

Thus through hole 63 in link 25' could carry shaft 37 and/or shaft 69, with, say, a bearing taken from whichever is the larger local diameter.

Similar buffer clamps can be fitted to the otherwise free end 39 of frame 22, or elsewhere, for additional clamping effect between either or both frames 21, 22 and container 10.

By varying the projection of the clamps, from one side to another, a vehicle and attendant support frame 22 can be located to one or other side of the container 10.

This can be used to advantage, by maximising lateral clearance between one side of vehicle and a container wall, for operator access to and from vehicle doors, without damage.

10 Clamps might also be deployed to reduce vehicle to side wall clearance, so inhibiting unauthorised vehicle access through an unlocked door.

In Figure 2A, lower depending link portion 25' is shown fitted with a downward bracing strut or leg 43, to engage the container floor 17.

The leg 43 also carries a profiled latching detent or cam 44, extending above pivot 37.

1 5 When drawn up to the stowage position, against roof 27, the cam 44 bears upon the roof 27 and draws leg 43 up generally horizontally, away from cargo.

It is envisaged that the links 25, 25' are semi-rigid and of fixed or adjustable span, such as with turn-buckles 62 (not detailed).

Such link adjustment would allow pivot shaft 37 to be raised or lowered, to reflect vehicle size or form, or general cargo profile to be accommodated above or below.

Figure 2C shows inset of (slender depth) side posts of an outer carrier frame, such as for the assembly of Figure 2A, within side wall corrugations.

Overall, a variety of different vehicle support configurations are envisaged.

26

Figures 3A and 3B show a variant vehicle support frame 82 mounting upon side posts 81 in conjunction with a cable suspension 85, and a depending leg or bracing strut 84, deployable to bear upon the container floor 17.

Each side of vehicle support frame 82 – which again may be configured as pair wheel ramps – is carried at one (rearward) end upon a side post 81, through a pivot mounting 87.

The post 81 is secured at its upper end by a pivot 83 in a mounting block 89 secured to an upper side frame of a container.

The arrangement is suitable for a curtain sided container, in which case the mounting block 89 can be configured as a traveller in an upper (curtain) guide rail, allowing overall longitudinal positional adjustment of the post 81.

Figure 3B shows a part collapse folded configuration of the support frame arrangement of Figure 3A.

By draw pull on cable 85, or supplementary cables post 81 is swung upwards, about pivot 83.

Support frame 82 is carried aloft, to a progressively more horizontal disposition, and bracing strut 84 is swung into alignment with juxtaposed frame 82 and post 81, for a compact overall collapse folded configuration adjacent the container roof underside.

The lower end of the post 81 could also be detachably mounted upon a lower curtain side rail guide, to relieve tension suspension loads.

Similarly, when the bracing strut 84 is engaged with the container floor, the tension in suspension cable 85 is relieved somewhat, or totally.

Reverting to Figure 2A, frame 22 might be extended, (in this case forwardly) beyond pivot 37, to allow vehicle end wheel travel beyond that point.

27

Thus the centre of gravity of a vehicle driven upon frame 22, with end wheels beyond pivot 37, will be closer to the pivot line R.

This achieves a more balanced 'see-saw' effect, about pivot 37 – reducing the suspension load in cables 19 to raise the frame 22 and vehicle 31.

Indeed links 24, 25' could be replaced altogether by cables, operable for independent (free suspended) variation of frame inclination and elevation.

With a fully extendible cable suspension at both ends, frames 21, 22 could be lowered flat upon the container floor 17, so that vehicles can drive on in a horizontal plane.

0 This is safer than progress along an inclined ramp.

Figures 8A and 8B show a double-ended cable support arrangement for a support frame 21, 22.

Longitudinally spaced cable pairs 162, 164 and 166, 168 are disposed to suspend different (in this case forward and rearward) ends of an underlying vehicle support frame (not shown).

Cables 162, 164 run over paired (upright) pulleys 177 and their upper ends are captured in a common traveller block 178 at one container side.

Cable 162 is brought across to the same side as cable 164 over paired horizontal transfer pulleys 175.

Traveller block 178 is threaded and carried upon a threaded stem 163, with a coupling eye 167, for a loop end 173 of a detachable handle 171.

Block 178 is prevented from rotation, as stem 163 rotates, by a rail 112, along which it slides fixed to the top rail 28.

28

Stem 163 is mounted in a bearing block 111, secured to side rail 28 and is fitted with a collar 112.

As tension in cables 162, 164, 166 and 168 develops, stem 163 is pulled by block 178 and is balanced

by collar 1 1 2 acting upon block 1 1 1.

In the arrangement shown, handle 173 can selectively operate either stem 161,163 from the rearward end of the assembly.

Rotation of the stem 163 by the handle 171 moves the traveller block 178 longitudinally, fore or aft, along the stem 163 and draws (lower ends of) cables 162, 164 upward or downward, together.

1 0 A similar arrangement for the other cable pair 166, 168, brings them over upright pulleys 174 and unites them at traveller block 179 running upon threaded stem 161, at the opposite side to traveller block 178.

Cable 168 is brought to the same side as cable 166 by horizontal transfer pulleys 172.

The same handle 171, once engaged with coupling eye 165, may be used to rotate 1 5 stem 161, for traveller block 179 and cable 166, 168 end adjustment.

This arrangement allows independent adjustment of cable pairs 162, 164 and 166, 168, for associated vehicle support frame ends – and thus frame tilt and elevation adjustment.

The thread pitch of stems 161, 163 allows some mechanical advantage, which may be enhanced with appropriate 'block and tackle' co-operative pulley sets in the cable runs – so manual operator adjustment is feasible, even with a frame loaded with a vehicle.

Figures 1A through 1 D show a vehicle support frame arrangement carried directly by the container (frame) – in particular suspension loads from the roof 27.

29

Figure 1 D includes a detail of an internal headspace 205, generally of depth equivalent to that of a container top end frame rail, and any header bar, and extending over the internal load platform footprint.

Figure 3C shows utilisation of this headspace 205 to accommodate a collapse folded, retracted vehicle support frame.

Figure 2A shows loading of top rails 28, through fixtures 51, 52 – which themselves could be secured to standard internal lashing eyes or loops.

Figure 2C shows a supplementary internal frame 70, to carry vehicle support frame loads.

1 0 The frame 70 comprises paired upright side posts 72, with a cross header rail 71 and (lug) fixtures 73 to receive cables 18, 19 or links 24, 25.

Posts 72 are located within opposed side wall corrugation 67 profiles, for minimal (lateral) load space intrusion ; clear of cars, cargo and personnel.

The feet of posts 72 can be located by spigot plates 75 plugged into gaps 56 5 between container floor 17 and bottom side rails 57.

The cross rail 71 might be omitted, given a suitable lashing point on the container top rail 28.

Posts 72 might be secured to container side walls 67. Within posts 72 could be accommodated a lift, such as a threaded stem 1 1 3, anchored at its top in a bearing block (not shown) to allow it to rotate.

Threaded upon stem 113 is a shoe 114 from which hang cables 115 to lift frame 22.

Rotation of stem 1 1 3 raises and lowers frame 22 via cables 1 1 5, which allowing a certain (longitudinal) displacement.

30

Container frame loading can be (re-) distributed by depending extension legs 43 on frame 22.

Legs 43 could be adjustable in span, to reach the container floor 17, and could slide transversely within block 65.

This would not only minimise their intrusion in to the container cargo space, but to allow a shift into side wall corrugations to assist in securing frames 21 @ 22.

Generally, support frames 21 @ 22 might be collapsible, or demountable, for ease of transport and storage when not needed.

Releasable fastenings or couplings (not shown) could be fitted between support 0 frames 21, 22 and container frame, even using existing internal load lashing points.

Although various vehicle support frame mountings have been described, they may be combined beyond the particular arrangements depicted.

Figures 1 A through 1 D are compatible with diverse container types, but are particularly addressed to solid panel side walls.

5 However, they could be adapted to work with an open lattice container frame structure – that is without necessarily reliance upon intervening wall or end panel infill.

Similarly, the lateral locking clamps of Figures 2A and 2B are intended to work in conjunction with solid side wall containers, and in particular corrugated sides.

Curtain Sided Container

Figures 3A–313 and 4A–413 are compatible with open – and in particular curtain – sided containers and trailers, in not relying upon side wall clamping.

Figures 5A–5C, 6, 7A–7D and 9 are compatible with corrugated solid side walls to accommodate side posts or with curtain sides.

31

Generally, vehicle support frames could be clamped between opposed side posts, themselves secured between container upper and lower side rails.

Figures 2A, 3A and 3B feature a strut or post spanning between container roof 27 and floor 17.

This allows load distribution to be adjusted – although a predominant hanging or suspension loading, and thus strut tension, may be retained.

The Figure 3A, 3B side posts 81 are configured to fit an open (curtain) side wall, using existing upper and lower side rail guides.

The post end fittings can thus be fitted with runners, to locate in those guide rails, 0 allowing longitudinal post adjustment.

A roller runner connection can also be employed between vehicle support frame and side post, to accommodate longitudinal pivot positional adjustment as the frame changes its elevation.

By uncoupling the lower post end from the lower guide rail, the post can be pivoted, 5 about its upper end carrier or rail runner – to a retracted position adjacent the container roof 27.

Similarly, longitudinal post tilt or inclination can be accommodated by relative movement of post top and bottom runners – with optional post (say telescopic) extendibility, for longer diagonal span.

Figure 4A shows an open (curtain) sided container, with (flexible fabric sliding side wall) curtain 105, running in a guide track 103 fitted under an upper side rail 98, supporting a roof panel 201.

A depending, resiliently deformable, or semi-rigid, side seal 109 is fitted between upper side rail 98 and curtain 105 as a weather barrier.

32

A supplementary side post guide track 1 01 is fitted, inboard of the curtain guide track 103, beneath the upper side rail 98, to carry a longitudinally movable side post 95.

The side post 95 supports a part-balanced, (vehicle support frame) ramp 92 through a pivot mounting 96.

In conjunction with the post 95, a (rearward) cable suspension 91 and (forward) articulated link 94 act at opposite sides of the pivot 96.

By virtue of the guide track 1 01 and pivot runner 102 top mounting, post 95 can be moved wholesale, or canted longitudinally, to adjust pivot 96 disposition – and thus ramp 92 tilt and/or elevation.

1 0 Similarly, some mobility of pivot 96 upon post 95 could be achieved with, say, a sliding mounting.

A corresponding bottom mounting 104 (not detailed) could be provided for the post 95, say using a lower guide track.

Figures 5A through 5C and 6 depict vehicle support frame variants which may be 1 5 adapted for (rigid) panel sided, or (soft) curtain sided containers, using longitudinally spaced support post pairs

Thus Figure 5A shows a container side wall 127 that could be rigid panel corrugations or a sliding (eg concertina folding) curtain.

Adjustable side posts 125 feature at both rearward and forward ends of (vehicle support) ramps 122.

Figure 5B details accommodation in hollow side posts 125 of screw jacking pillars 121.

A traveller 128, with an inward spigot 126, runs upon a screw pillar 121, for pivot mounting ramp 122, allowing tilt and elevation.

33

Side posts 125 span between upper and lower container side rails, with an upper mounting 129 and lower mounting 124.

End mountings 124, 129 may be adjustable, for side post 125 pivot and/or movement longitudinally, to accommodate ramp 122 disposition.

Similarly, an intermediate roller slide, mounting 126 between side posts 125 and ramps 122 accommodates ramp 122 (re-)orientation (tilting) and (re-)disposition (elevation).

Side posts 125 may be suspended from respective upper mountings 129 and can feature a motorised pivot, for post 125 retraction folding.

1 0 Generally, either or both forward and rearward side post pairs 125 could be moved longitudinally, together or differentially, for ramp 122 orientation.

Figure 5C shows an articulated or swing link 132 and free cable suspension 131 for local interconnection of ramp 122 and screw jack pillar runner 128.

Figure 6 shows ramps substituted by transverse wheel carriages 134, 136 of open 1 5 lattice form, allowing wheel capture between rungs.

This arrangement allows independent movement of front or rear wheel pairs.

As the wheel support plane between carriages 134, 136 tilts, vehicle body disposition can adjust about the captured wheels.

That said, the carriages 134, 136 could themselves tilt about respective transverse axes, that is about spigot mountings 126, to accommodate vehicle tilt.

Once the carriages 134, 136 have stabilised, they could be secured to their respective suspension elements (whether cables or screw jack pillars) by a bracing and clamping arrangement, such as shown in Figures 7G and 7H.

34

Again longitudinal post travel in upper and lower guide rails could also accommodate differential vehicle span.

Figures 7A through 7D show other suspended wheel carriage or cradle configurations.

Figure 7A shows wheel carriages 144, 146 between upper links 141, 143 and lower struts 148, 149, to share loads between container roof 27 and floor 17.

Struts 148, 149 are either fixed or adjustable (eg telescopic) span, generally upright, single pillars.

Figure 7B shows wheel carriage underside support by adjustable crossed-leg, or 10 scissor-jacks 151, 153.

Figure 7C shows wheel carriage underside support by trestles 155, 157, with fixed or adjustable splay longitudinal bracing legs.

Figure 7D shows wheel carriage underside support by a combination adjustable single and multiple splayed extension leg trestles 158, 159.

15 Figures 7A and 7B use primary suspension cables and/or depending links 141, 143, with diagonal cross-bracing wires 145, 147, for longitudinal stability.

Figures 7C and 7D rely upon underlying trestle bracing longitudinally.

The adjustable cable suspension of Figures 8A and 8B can be used in conjunction with the arrangements of Figures 7A through 7C.

Figures 7E through 7H show wheel suspension cradle refinements, including local tyre protrusion as a buffer, vehicle re-orientation about a suspended wheel pivot, cradle to suspension cable bracing upstand 154 and releasable cable clamp 154.

35

The upstand 154 and clamp 154 inhibit cradle swing upon the suspension cables.

An inverted parking position for cradle 146 is shown in outline, allowing it to be retracted into the container internal roof headspace 205 (Figure 1 D).

Cable suspension could be substituted with suspended screw jacking pillars, again hung from the container roof frame structure.

The vehicle support assembly could be removable and (re-)installable in its entirety.

Thus the vehicle support assembly could be configured as a demountable (overhead) gantry or crane structure, secured to existing internal container frame lashing points, by detachable fastenings or ties (not shown)

0 Figure 9 shows the vehicle support assembly configured within a container extension module 230, (de-)mountable upon an open top container 210.

A similar configuration could be employed for, say, a flat rack container, as a gantry between end walls upstanding upon a base platform (not shown).

Mounting is through standard corner block mounting blocks 212, 214 and internal 5 couplings, such as TwiSTLOCKS, for overall container handling and stacking, as an integrated unitary entity.

Extension module 230 carries vehicle support frames 221, 222, with associated cable suspensions 218, 219 and articulated links 224, 225.

Vehicles 231, 233 are carried at an upper level upon support frames 221, 222.

This generally reflects the arrangements of Figures 1 A through 1 D, so will not be described further.

The collapse folded mode of the frames 221 t 222 is within the depth confines of the extension module 230, affording protection.

36

The module 230 could then be uncoupled from the underlying open top container 210 and used with another container or stored.

A peripheral seal (not shown) may be installed between extension module 230 and underlying open top container 210.

Claim:

1 .
 A vehicle support, for a container (1 0),
 comprising a frame (21 P 22),
 suspended from one or more elements (19, 25). 2.
 A vehicle support,
 as claimed in Claim 1,
 with one or more elements of adjustable span,
 1 0 to vary frame disposition,
 such as elevation and/or tilt,
 from an (un)loading to a transport mode. 3.
 A vehicle support,
 1 5 as claimed in either of the preceding claims,
 wherein the frame is hung,
 from at or adjacent an end,
 by a cable suspension.
 44

A vehicle support,
 as claimed in any of the preceding claims,
 wherein the frame is hung,
 from at or adjacent an end,
 by one or more depending links. 5.
 A vehicle support,
 as claimed in any of the preceding claims,
 0 wherein the frame is hung,
 from at or adjacent an end,

by a jacking screw pillar. 6.

A vehicle support,

5 as claimed in any of the preceding claims,
configured for collapse,
into a compact folded retracted condition. 7.

A vehicle support,

as claimed in any of the preceding claims,
configured for collapse,
into a compact folded retracted condition,
within an internal roof headspace.

45

A vehicle support,

as claimed in any of the preceding claims,
fitted with a retractable suspension element. 9.

A vehicle support,

as claimed in any of the preceding claims,
with a frame configured as wheel ramps,
for vehicle support. 10 10.

A vehicle support,

as claimed in any of the preceding claims,
with a demountable (un) loading ramp,
configured for external access,
15 but stowable internally,
by carriage with the support frame
towards the container roof,
upon a collapsed mode. 11.

A vehicle support,

as claimed in any of the preceding claims,
with a frame configured as a wheel sling, cradle or carriage, for vehicle support.

46

A vehicle support,

as claimed in any of the preceding claims,
incorporating [adjustable] bracing,
[longitudinally and/or transversely]
between frame and container. 13.

A vehicle support,

as claimed in any of the preceding claims,
10 incorporating extendible [screw] jacks,
to engage container side walls or side posts,
for longitudinal and/or transverse bracing,
between frame and container. 14.

15 A vehicle support,

as claimed in any of the preceding claims,
incorporating extendible [screw] jacks,
with profiled end buffers,
to engage corrugation recesses or side posts,
in container side walls,
for longitudinal and/or transverse bracing,
between frame and container.

47

A vehicle support,

as claimed in any of the preceding claims,
incorporating a retractable bracing strut,
between frame and container [floor]. 16.

A vehicle support,

as claimed in any of the preceding claims,
with lateral support posts,
0 between container roof and floor,
for adjustable frame mounting. 17.

A vehicle support,

as claimed in any of the preceding claims,
5 with lateral support posts,

suspended from a container upper side rail. 18.
A vehicle support,
as claimed in any of the preceding claims,
with lateral support posts,
incorporating screw jacking pillars,
with pivot carriage runners,
for movable frame support.
48

A vehicle support,
as claimed in any of the preceding claims,
with lateral support posts,
incorporating screw jacking pillars,
suspended from a container upper side rail. 20.
A vehicle support,
as claimed in any of the preceding claims,
1 0 with lateral support posts,
configured for recessed disposition,
in container side wall corrugations. 21.
A vehicle support,
1 5 as claimed in any of the preceding claims,
configured to accommodate mixed
vehicle and general cargo. 22.
A vehicle support,
as claimed in any of the preceding claims,
with a cable winch,
for adjustable frame suspension.
49

A vehicle support,
as claimed in any of the preceding claims,
with a motorised link suspension,
for adjustable frame suspension. 24.
A vehicle support,
as claimed in any of the preceding claims,
with a [self-contained] support gantry,
0 for adjustable frame support. 25.
A vehicle support,
as claimed in any of the preceding claims,
configured for a flat rack container,
5 and carried between end walls,
upstanding from a base platform. 26.
A vehicle support,
as claimed in any of the preceding claims,
configured for a curtain sided container,
with lateral support posts,
movably mounted in guide rails.
50

A vehicle support,
as claimed in any of the preceding claims,
configured for a curtain sided container,
with lateral support posts,
movably mounted in guide rails,
and an [adjustable] pivot connection,
with a vehicle support frame,
to accommodate frame (re-)disposition,
1 0 by post and/or pivot movement. 28.
A vehicle support,
as claimed in any of the preceding claims,
configured for a curtain sided container,
1 5 with lateral support posts,
movably mounted in guide rails,
disposed alongside curtain guide rails,
upon a container upper side frame. 29.

A vehicle support,
as claimed in any of the preceding claims,
configured as an overall demountable structure,
for installation in and removal from a container.
51

A vehicle support,
as claimed in any of the preceding claims,
configured as a demountable overhead structure,
such as gantry within an extension module,
upon an open top container. 31.

A vehicle support,
as claimed in any of the preceding claims,
1 0 fitted with safety suspension ties,
to which the support frame is secured,
once elevated,
as a backup to suspension lift elements. 32.

1 5 A vehicle support,
as claimed in any of the preceding claims,
with suspension lift elements,
configured for accommodation
within a container frame structure.
52

A vehicle transport and storage
adaptation or conversion frame,
for a container,
with a vehicle support,
as claimed in any of the preceding claims. 34.

A container,
with a [collapsible] vehicle support,
1 0 as claimed in any of the preceding claims.

INTERNATIONAL SEARCH REPORT

Int. Application No

PCT/GB 01/04413

A. CLASSIFICATION OF SUBJECT MATTER
 IPC 7 B65D90/00 B60P3/08 //B65G90/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 B65D B60P

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 4 801 229 A (KATO YUJI ET AL) 31 January 1989 (1989-01-31) the whole document	1-3, 8, 9, 11, 12, 15, 21-25, 31-33
X	US 4 797 049 A (GEARIN PETER ET AL) 10 January 1989 (1989-01-10) column 4, line 9.-column 6, line 13; figures 2,5-7 --- -/-	1, 11, 14-17, 21, 24, 29, 30, 32

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *Z* document member of the same patent family
